Introduction

The MapleSim™ FMI Connector and FMI Connector package provides all of the tools you need to prepare and export your dynamic systems models into an FMU (Functional Mock-up Unit) archive file.

You can create a model in MapleSim, simplify it in Maple™ by using an extensive range of analytical tools, and then generate FMU executables that you can incorporate into your toolchain. Using MapleSim Insight (a separate product), you can see live simulation results and 3-D visualizations of your models that run in real-time.

Scope of Model Support

MapleSim is a comprehensive modeling tool where it is possible to create models that could go beyond the scope of this FMI Connector. In general, the MapleSim FMI Connector supports systems of any complexity, including systems of DAEs of any index, in any mix of domains.

Requirements

Windows users need to install a third-party 'zip' utility which must be included in the PATH environment variable in order to successfully generate an FMU.

For details on supported platforms and a complete list of system requirements, visit the Maplesoft System Requirements website at http://www.maplesoft.com/products/system_requirements.aspx.

For installation instructions, see the **Install.html** file on the product disc or the website at http://www.maplesoft.com/documentation_center/installation_instructions.aspx.

Distribution of an FMU

Under the terms and conditions of the Maplesoft End User License Agreement, you have the right to use an FMU created with the MapleSim FMI Connector within your organization. **If you wish to distribute this FMU outside your organization, you must first obtain a FMU Commercial Distribution License from Maplesoft.** For more information, refer to the **FMU Distribution** help page.

Adding External Libraries to Your Search Path

You can export a model that uses an external library as part of the model to an FMU archive. In order to do this, you **first** need to add the directory that contains the external library file (that is, the .dll or .so file) to your search path. This involves appending the external library directory to either your PATH environment variable (for Windows®) or your LD_LIBRARY_PATH environment variable (for Linux® and Macintosh®).

To add an external library directory to your search path

1. Determine the location of the external library directory.

Note: This is the directory that contains the .dll file (Windows) or the .so file (Linux or Macintosh) that is used in your model.

2. Add the library directory found in step 1 to the appropriate environment variable for your operating system.
 - For Windows, add the library directory to your PATH environment variable.
 - For Linux and Macintosh, add the library directory to your LD_LIBRARY_PATH environment variable.

Consult the help for your operating system for instructions on how to edit these environment variables.

3. Restart your computer.

1 Getting Started

1.1 FMI Code Generation Steps

This chapter describes how to use the FMI app and in the *Example: RLC Circuit Model (page 8)* section of this chapter, a step by step procedural example shows you how to create an FMU archive file. The **FMU Generation** app consists of the following steps to generate C code:

1. Subsystem selection
2. Inputs/Outputs and parameter management
3. FMI code generation options
4. Generate FMI C code
5. View generated FMI C code

The FMI Connector package

The FMI Connector package is a collection of procedures for manually generating and compiling FMI code from MapleSim models. For information about the FMI Connector package, in Maple, refer to the **FMConnector** help page.

1.2 Opening the FMU Generation App

To open the FMU Generation app:

1. From the main toolbar in MapleSim, click **Show Apps Manager** .
2. Double-click the **FMU Generation** entry in the **Apps** palette. The **FMU Component Code Generation** app opens.
3. In the **Subsystem Selection** section, select a subsystem from the drop down list.

1.3 Using the FMU Generation App

The MapleSim FMI Connector provides an **FMU Generation** app for manipulating and exporting MapleSim subsystems as FMU archive files.

With this app, you can define inputs and outputs for the system, set the level of code optimization, generate the source code, and choose the format of the resulting FMU component and library code. You can assign model equations to a variable, group inputs and outputs, and define additional input and output ports for variables.

Note: FMU component generation now handles all systems modeled in MapleSim, including hybrid systems with defined signal input (RealInput) and signal output (RealOutput) ports.

Example models are available in MapleSim. To access these, from the **Help** menu, select **Examples > FMI Connector Examples**.

Step 1: Subsystem Selection

This part of the app identifies the subsystem modeling components that you want to export as a block component.

To connect a subsystem to modeling components outside of its boundary, you add subsystem ports to your model. A subsystem port is an extension of a component port in your subsystem. The resulting signals can then be directed as inputs and outputs for the FMU archive files. By creating a subsystem you improve the visual layout of a system in the model workspace and also prepare the model for export. The example in Chapter 2 shows you how to group all of the components into a subsystem.

You can select which subsystems from your model you want to export to an FMU archive file. After selecting a subsystem, click **Load Selected Subsystem**. All defined input and output ports are loaded.

Load Selected Subsystem

Step 2: Inputs, Outputs, and Parameters

The **Inputs**, **Outputs**, and **Parameters** sections let you customize, define, and assign parameter values to specific ports. Subsystem components to which you assign the parameter inherit a parameter value defined at the subsystem level.

After the subsystem is loaded you can group individual input and output variable elements into a vector array, and add additional input and output ports for customized parameter values. Input ports can include variable derivatives, and output ports can include subsystem state variables. You can specify prefixes for both input and output port variables. The prefix for the input (output) port variables will be applied to all the variables in the input ports (outputs) table.

▼	R1_alpha	<input type="radio"/> Tunable

value: 1.

Use fully qualified names for FMU

Note: If the parameters are not marked for export they will be numerically substituted. Parameters marked as tunable will also be marked for export by default. However, tunable parameters will be ignored if FMI Version and Environment (see Step 3: Export Options) are anything other than Co-Simulation. To use fully qualified parameter names for the generated FMU, check the corresponding check box; otherwise, short parameter names will be used by default.

Step 3: Export Options

Select **Export Options** to specify the advanced options for the code generation process. Default settings are provided for both Model Exchange and Co-Simulation export options.

FMI Version and Environment

Select the FMI version and environment for your code. You can choose between **FMI 2.0** and **FMI 3.0** for the version. For FMI 2.0 you can also choose between Model Exchange and Co-Simulation for the FMU type, the FMI 3.0 export includes interfaces for both.

FMI Version: 2.0 3.0

FMI Type: ME CS

Include MapleSim Insight data

View advanced FMU settings

Select **Include MapleSim Insight data** to include the necessary data for the FMU to be run with MapleSim Insight (available as a separate product).

Select **View advanced FMU settings** to see Constraint Handling, Event Handling, Code Generation, and Solver options.

To match the MapleSim model's current simulation settings, click the **Match Simulation Settings** button. (Note that you can revert to the default settings for Model Exchange and Co-Simulation using the refresh button  at the top of the app window.)

Co-Simulation Solver Settings

For the Co-Simulation interface, the Co-Simulation Solver can be set to Euler, RK2, RK3, RK4, Implicit Euler, CK45, or Rosenbrock. The communication step size can also be specified.

FMI Version: 2.0 3.0

FMI Type: ME CS

Include MapleSim Insight data ?

View advanced FMU settings

Co-Simulation Solver:

Euler RK2 RK3 RK4 Implicit Euler CK45 Rosenbrock

↔ Faster More stable ↔

Communication step size:

Advanced FMU Settings

Select View advanced FMU Settings to make further modifications.

You can specify Solver Options for the chosen solver.

Solver Options:

of internal steps:

Internal step size: 0.001

Allow additional steps for events

of allowed steps:

Tolerance:

Jacobian: Numeric Symbolic

Jacobian: In the case of the Implicit Euler solver, specify either numeric or symbolic formulation for the system Jacobian.

Constraint Handling Options

Baumgarte stabilization

Alpha: Beta:

Proj. iterations:

Proj. tolerance:

Event Handling Options

Event Projection

Event iterations:

Init. hysteresis:

Code Generation Options

Add directional derivatives

Optimize for fixed-step solver

Allow input deriv. ports

Detailed run-time errors

Add extended variables

The Constraint Handling Options specify whether the constraints are satisfied in a DAE system by using constraint projection in the generated FMU archive file. Use this option to improve the accuracy of a DAE system that has con-

straints. If the constraint is not satisfied, the system result may deviate from the actual solution and could lead to an increase in error at an exponential rate.

The Baumgarte constraint stabilization method stabilizes the position constraint equations, by combining the position, velocity, and acceleration constraints into a single expression. By integrating the linear equation in terms of the acceleration, the Baumgarte parameters, alpha and beta, act to stabilize the constraints at the position level.

Baumgarte stabilization: Apply the Baumgarte constraint stabilization.

Alpha: Set the derivative gain for Baumgarte constraint stabilization.

Beta: Set the proportional gain for Baumgarte constraint stabilization.

Set the **Projection iterations** to specify the maximum number of times that a projection is permitted to iterate to obtain a more accurate solution.

Set the **Projection tolerance** to specify the desirable error tolerance to achieve after the projection.

The Event Handling Options specifies whether the events are satisfied in a DAE system by using event projection in the generated FMU archive file. Use this option to improve the accuracy of a DAE system with events. If the constraint is not satisfied, the system result may deviate from the actual solution and could lead to an increase in error at an exponential rate.

Set the **Event iterations** to specify the maximum number of times that a projection is permitted to iterate to obtain a more accurate solution.

Set the **Initial hysteresis** to specify the desirable error tolerance to achieve after the projection.

Select **Event projection** to perform event projection using the **event projection** routine in the External Model Interface as described on The MathWorks website to control the drift in the result of the DAE system.

Note: Currently, if the model has events, they are handled using the event handling functions in the generated Msim-Model.c file, and not the FMI provided Event Handling routines.

The Code Generation Options control details of the generated code and run-time errors.

Add directional derivatives: Select the check box to generate directional derivatives code. **Note:** This option is expensive; use only when required.

Optimize for fixed-step solver: Specifies if the generated code should be optimized for use with fixed-step solvers.

Allow input deriv. ports: Specifies if ports can be added for derivatives of inputs, if needed. Otherwise, numerical derivatives are computed.

Detailed run-time errors: Report run-time errors in detail.

Add extended variables: Choose between minimal and extended variable tracking during the simulation.

Step 4: Info Options

In the generated FMU archive file, model information (for example, variable names, units and initial values) are stored in a text file in XML format. Additional information about the model, such as the model author, description, and version, can also be included in this file.

Author:

Description:

Version:

Copyright:

License:

Author: Name and organization of the model author (for example, J. Smith, Maplesoft <http://www.maplesoft.com>).

Description: Brief description of the model (for example, Model of a lithium-ion battery).

Version: Model version or FMU version.

Copyright: Intellectual property copyright (for example, (C) Maplesoft 2024).

License: Intellectual property licensing (for example, Proprietary, Public Domain, or BSD License).

Step 5: Export

Generating the C code creates temporary files for viewing purposes.

Export

Target directory:

FMU Archive Name:

Selected Compiler: LLVM

FMU Distribution Type: DLL/Shared Object Source Code Only

Remove Source Files from the FMU Archive Remove temporary 'fmiTMPXXXXXX' directory

Overwrite

Specify the location for the **Target Directory**.

Provide a name for the generated FMU archive in **FMU Archive Name**.

Specify the FMU Distribution Type to DLL/Shared Object or Source Code Only.

Select **Remove Source Files from the FMU Archive** to remove source files after code generation.

Select **Remove temporary `fmiTMPXXXXXX` directory** to remove temporary files after code generation.

Specify whether to overwrite an existing FMU archive, if present.

To generate an FMU archive click **Generate FMU Archive**. The FMU is generated.

Note: If your model contains an external library, you must add the directory that contains the external library to your search path. See *Adding External Libraries to Your Search Path (page iv)* for instructions on how to do this.

Step 6: View Code

After the C code is generated, the **FMI C Code** and **MsimModel.c** components can be viewed.

1.4 Note on Ports for Derivatives

When the derivative of an input is required in the FMU, the FMU Generation app adds additional ports to the FMU that allow the user to directly define these. This avoids the numerical differentiation of these values, which can be unstable at the start of a simulation.

If ports for derivatives are created, their names will be of the form $VariableName_{der}$ (first derivative) or $VariableName_{der_{der}}$ (second derivative).

1.5 Viewing Examples

Within MapleSim there are many examples for you to view.

To view an example:

- From the **Help** menu, select the **Examples > FMI Connector Examples** menu, and then click the entry for the model that you want to view.

Some models include additional documents, such as Maple worksheets. For example, the **Double Wishbone** example has an attached Maple worksheet, **DefiningHardPoints.mw**. To view an attached Maple worksheet:

4. From the main toolbar in MapleSim, click the Load a Maple Worksheet icon ()
5. Select the document from the list of attached worksheets, and click OK. The worksheet opens in Maple.

Alternatively, all attachments to a MapleSim model can be found under the **Attached Files** tab (). You can right-click (**Control**-click, for Mac) on an attachment and select **View** to open it in Maple (for Maple worksheets) or in the appropriate program.

1.6 Example: RLC Circuit Model

In this example, you will generate an FMU archive file using an RLC circuit model created in MapleSim.

To generate an FMU archive file:

1. From the **Help** menu, select **Examples > FMI Connector Examples**, and then select the **RLC Parallel Circuit** example.
2. From the main toolbar, click **Show Apps Manager** ().
3. Double-click the **FMU Generation** entry in the **Apps** palette. The **FMU Component Code Generation** app opens.
4. Select the **RLC** subsystem from the drop-down list in the **Subsystem Selection** section. This menu displays all of the subsystems and components in your MapleSim model.
5. Click **Load Selected Subsystem**. All of the app fields are populated with information specific to the subsystem displayed in the model diagram. You can now specify which subsystem parameters will be kept as configurable parameters in the generated block.
6. In the **Export** section of the app, specify the target directory and the FMU archive name.
7. Click **Generate FMU Archive**. The .fmu zip file is created and saved in the target directory.

Note: Generating a block may require a few minutes.

2 Example: Exporting a Model as an FMU File

2.1 Preparing a Model for Export

In this example, you will perform the steps required to prepare a slider-crank mechanism model and export it as an FMI file.

1. Convert the slider-crank mechanism model to a subsystem.
2. Define subsystem inputs and outputs.
3. Define and assign subsystem parameters.
4. Export the model using the FMI file Generation app.

To open the slider-crank mechanism example:

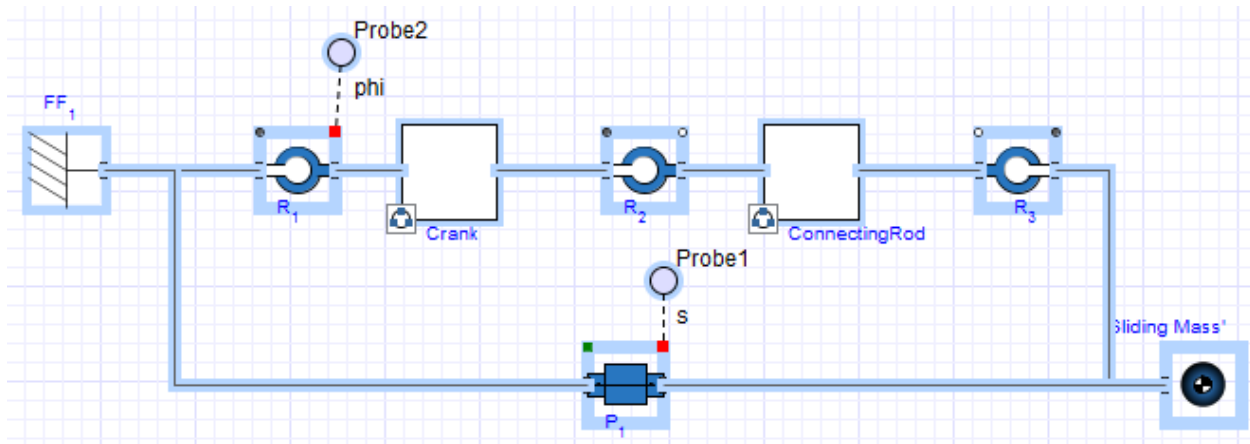

1. In MapleSim, click the **Help** menu item.
2. Select **Examples > User's Guide Examples > Chapter 6**, and then select **Planar Slider-Crank Mechanism**.

Converting the Model to a Subsystem

By converting your entire model or part of your model into a subsystem, you identify which parts of the model you want to export. Since the FMI connector supports data signals and properties on acausal connectors such as mechanical flanges and electrical pin, in this example, you will group all of the components into a subsystem and use an acausal input into the subsystem.

To create a subsystem:

1. Draw a box around all of the components in the model by dragging your mouse over them.

2. From the **Edit** menu, select **Create Subsystem**.
3. In the **Create Subsystem** dialog box, enter **SliderCrank** as the subsystem name.
4. Click **OK**. A **SliderCrank** subsystem block appears in the model workspace.

Defining Subsystem Inputs and Outputs

MapleSim uses a topological representation to connect interrelated components without having to consider how signals flow between them, whereas traditional signal-flow modeling tools require explicitly defined system inputs and outputs. In this example, since FMI supports causal and acausal ports, a torque driver is used as an input to the subsystem in MapleSim and for the FMU file.

You will convert the displacements of the slider and the joint between the crank and connecting rod to output signals. The input will be a torque driver that is applied to the revolute joint that represents the crank shaft.

To create a subsystem output port:

1. Double-click the subsystem block to view its contents. In this view, the broken line indicates the subsystem boundary. You can edit the connection lines and components within the boundary, and add subsystem ports to connect the subsystem to other components.
2. Delete the probes that are attached to the model.
3. In the **Library Components** tab () on the left side of the MapleSim window, expand the **Multibody** palette and then expand the **Sensors** submenu.
4. Drag the **Absolute Translation** component to the **Model Workspace** and place it below the **Prismatic Joint** component.

5. Right-click (**Control-click** for Mac®) the **Absolute Translation** component and select **Rotate Counterclockwise**.
6. From the **Signal Blocks** > **Routing** > **Demultiplexers** menu, drag a **Real Demultiplexer** component to the **Model Workspace** and place it to the right of the **Absolute Translation** component.

7. To connect the **Absolute Translation** component to the model, click the frame_b connector. The frame is highlighted in green when you hover your pointer over it.

8. Draw a vertical line and click the connection line directly above the component. The sensor is connected to the rest of the diagram.

9. In the same way, connect the **r** output port (*TMOutputP*) of the **Absolute Translation** component to the input port of the demultiplexer. This is the displacement signal from the sensor in x, y, and z coordinates. Since the slider only moves along the x axis, the first coordinate must be an output signal.

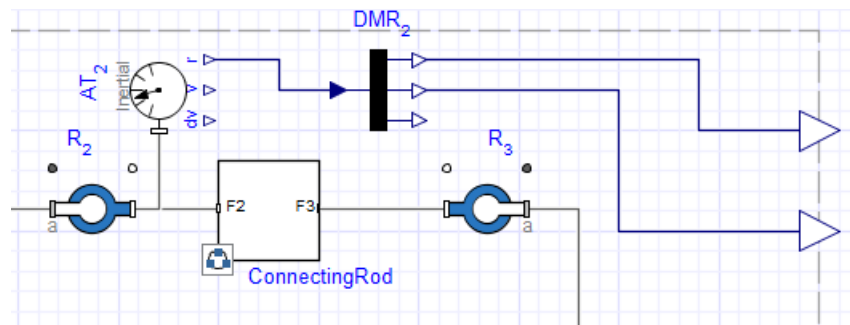

10. Hover your pointer over the first demultiplexer port and click your mouse button once.

11. Drag your pointer to the subsystem boundary and then click the boundary once. A real output port is added to your subsystem.

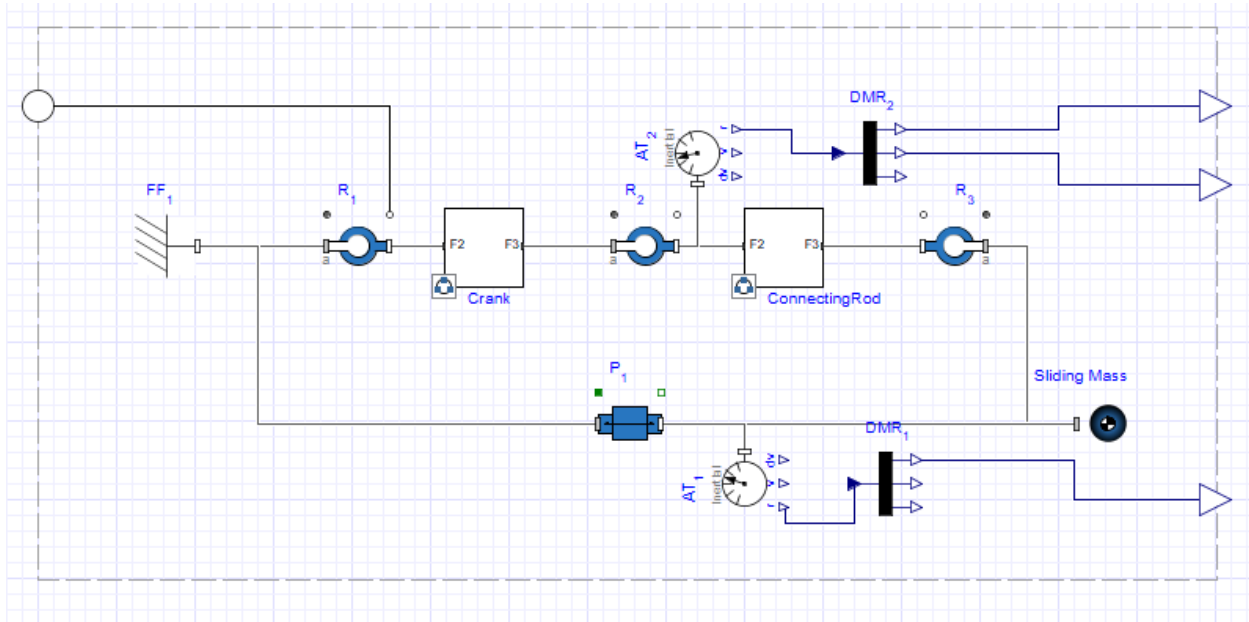

12. Add another **Absolute Translation** component above the **Connecting Rod** subsystem.
13. Right-click (**Control-click** for Mac) the **Absolute Translation** component and select **Flip Vertical**. Right-click the **Absolute Translation** component again and select **Rotate Clockwise**.
14. Add a **Real Demultiplexer** component to the right of the sensor and connect the components as shown below. Since the crank is moving in the x, y plane, you only need to output the first two signals. You are now ready to add a real input port to your subsystem to control the torque on the crank shaft.

15. Click on the white flange of the leftmost **Revolute Joint** and drag the pointer to the left boundary. This will act as the acausal input connection to the subsystem.

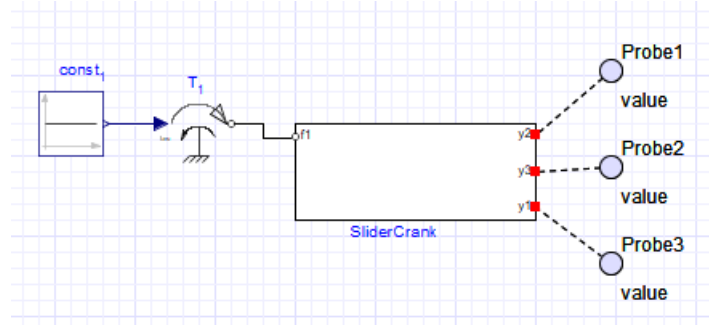

The complete subsystem appears below.

16. Click **Main** (🏠) in the **Model Workspace** toolbar to browse to the top level of the model.
17. From the **1-D Mechanical > Rotational > Torque Drivers** menu, add a **Torque** component to the **Model Workspace** and place it next to the subsystem.
18. From the **Signal blocks > Common** menu, add a **Constant** signal component to the **Model Workspace** and next to the Torque component and connect it to the Torque component.

19. Click **Attach Probe** (⊕) above the **Model Workspace** toolbar and then click the top output port of the **SliderCrank** subsystem.
20. In the **Model Workspace**, click the probe once to position it.
21. In the same way, add probes to the other **SliderCrank** output ports as shown below.

2.2 Defining and Assigning Subsystem Parameters

You can define custom parameters that can be used in expressions in your model to edit values more easily. To do so, you define a parameter with a numeric value in the parameter editor. You can then assign that parameter as a variable to the parameters of other components; those individual components will then inherit the numeric value of the parameter defined in the parameter editor. By using this approach, you only need to change the value in the parameter editor to change the parameter values for multiple components.

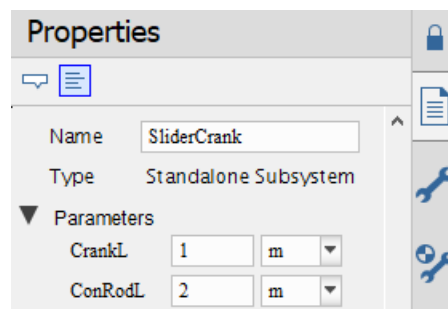

To edit parameters

1. Double-click the **SliderCrank** component on the Model Workspace to see the detailed view of the **SliderCrank** subsystem, and then click **Parameters** (📄) in the **Model Workspace** toolbar. The parameter editor appears.
2. In the first **Name** field, type **CrankL** and press **Enter**.
3. Change the **Type** to Length from the drop-down menu.
4. Specify a default value of **1m** and enter **Crank length** as the description.
5. In the second row of the table, define a parameter called **ConRodL** and press **Enter**.
6. Change the **Type** to Length from the drop-down menu.
7. Specify a default value of **2m** and enter **Connecting Rod Length** as the description.

Standalone Subsystem default settings

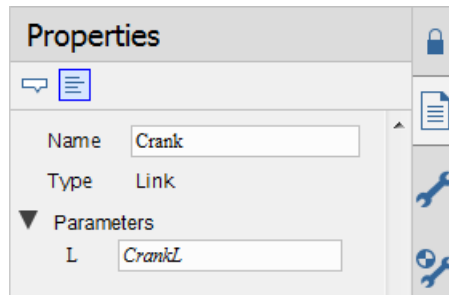

Name	Type	Default Value	Default Units	Description
CrankL	Length [m]	1	m	Crank Length
ConRodL	Length [m]	2	m	Connecting Rod Length

8. Click **Diagram View** (🏠) to switch to the diagram view, and then click **Main** (🏠).
9. Select the **SliderCrank** subsystem. The parameters are defined in the **Properties** tab (📄).

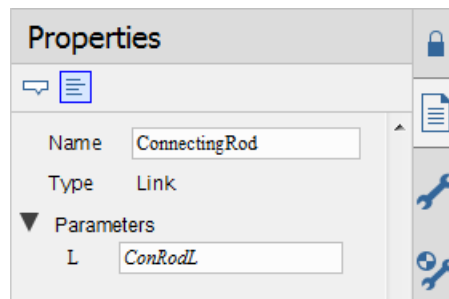

10. Double-click the **SliderCrank** subsystem, and then select the **Crank** subsystem.

11. In the **Properties** tab (📄), change the length value (**L**) to **CrankL**. The **Crank** subsystem now inherits the numeric value of **CrankL** that you defined.

12. Select the **ConnectingRod** subsystem and change its length value to **ConRodL**.

13. Click **Main** (🏠) in the **Model Workspace** toolbar to navigate to the top level of the model. You will include these parameter values in the model that you export. You are now ready to convert your model to an FMI block.

2.3 Exporting Your Model Using the FMU File Generation App

After preparing the model, you can use the FMU Generation app to set export options and convert the model to an FMU file.

To generate an FMU file

1. In the main toolbar in MapleSim, click **Show Apps Manager** (📄). The Analysis window opens with Apps tab selected.
2. Double-click on the **FMU Generation** entry under FMI Connector in the **Apps** palette. The **Analysis** window opens with the **FMU Component Code Generation** app loaded in the **Apps** tab.
3. In the **Subsystem Selection** section, select the **SliderCrank** subsystem from the drop-down list, and then click **Load Selected Subsystem**. All of the app fields are populated with information specific to the subsystem.
4. Since this example uses an acausal 1D - mechanical rotational flange, on selecting the **input** option, you have the option to either choose a torque or an angle input that can be fed into the subsystem.

Inputs Outputs Parameters Export Options Info Options
